

Practical-4

Aim: Implementation and Time analysis of factorial program using iterative and recursive method.

Algorithm:

Program:

1) Recursive method:

```
#include <iostream>
```

```
using namespace std;
```

```
int factorial(int n)
```

```
{
```

```
    if (n == 0 || n == 1)
```

```
        return 1;
```

```
    else
```

```
        return n * factorial(n - 1);
```

```
}
```

```
int main()
```

Name:D.Himabindu

Enrollment no:92400118934

```
{
    int n;

    cout << "Enter a number: ";

    cin >> n;

    cout << "Factorial using Recursive Method = " << factorial(n);

    return 0;
}
```

Output:

```
Enter a number: 5
Factorial using Recursive Method = 120

=== Code Execution Successful ===
```

Time complexity:

Time complexity + Recursive method

```

if (n == 0 || n == 1) → 1
return 1; → 1
return n * factorial(n-1); → n
}

int main() {
    int n; → 1
    cout << "Enter n: "; → 1
    cin >> n; → 1
    cout << "factorial" → 1
    cin << factorial(n); → n
    return 0; → 1
}

```

$T(n) = 1 + 1 + 1 + n + 1 + 1 + (n-1) + 1$
 $T(n) = 3n + 4$
 $T(n) = O(n)$ — Avg case

Best case → when $n=0$ (or) $n=1$, the base condition is immediately satisfied, so there is only one recursive call $O(1)$.

Average case → for a normal input such as $n=5$, the function makes approximately n recursive calls $O(n)$.

worst case → for a large input, the function continues recursive until it reaches $n=1$, resulting in recursive calls $O(n)$.

2) Iterative Method:

Algorithm:

Program:

```
#include <iostream>

using namespace std;

int main()
{
    int n, fact = 1;

    cout << "Enter a number: ";
    cin >> n;

    for (int i = 1; i <= n; i++)
    {
        fact = fact * i;
    }
}
```

```
cout << "Factorial using Iterative Method = " << fact;
```

```
return 0;
```

```
}
```

Output:

```
Enter a number: 3
Factorial using Iterative Method = 6
```

```
=== Code Execution Successful ===
```

Time complexity:

Time complexity

```

int main() {
    int n;
    long long fact = 1;
    cout << "enter the value of n: ";
    cin >> n;
    for (int i = 1; i <= n; i++) {
        fact = fact * i;
    }
    cout << "factorial = " << fact;
    return 0;
}

```

$T(n) = 1 + 1 + 1 + 1 + 1 + (n+1) + n + n + 1 + 1$
 $T(n) = 8n + 9$

Best case: $T(n) = O(n)$

Average case: $O(n)$ In the iterative factorial program the number of iterations not depend on the type of value of the input n , the loop always execute exactly n times.

worst case: The loop always executes n times even in the worst case of the iteration $O(n)$

Design and analysis of algorithm – 01AI0506

Conclusion:

The factorial program was successfully implemented using both iterative and recursive methods. The iterative method has $O(n)$ time and $O(1)$ space complexity, while the recursive method has $O(n)$ time and $O(n)$ space complexity due to the recursive call stack.
